

# Can We Represent Infinite Lists?

Certain collections are **infinite**, like the set of all natural numbers. We may try

```
fun all_numbers n =  
    n :: (all_numbers (n+1))
```

which has type

```
int -> int list
```

but

```
all_numbers 1
```

does **not terminate** and hence produces **no result**.

### Larger Examples

Primes  
Giving Change

Key idea:

- ▶ evaluate lists one element at a time
- ▶ generate an element only when **needed**
- ▶ the list tail is thus not fully evaluated yet

We may thus attempt

```
fun all_numbers n =  
  n :: (fn () => all_numbers (n+1))
```

but this is not quite type correct.

# Lazy Lists

```
datatype 'a lseq =
  Nil
| Cons of 'a * (unit -> 'a lseq)
```

We define `hd`, `tl` with types

```
hd: 'a lseq -> 'a   tl: 'a lseq -> 'a lseq
```

```
exception Empty
fun hd Nil = raise Empty
|   hd (Cons (x, _)) = x
fun tl Nil = raise Empty
|   tl (Cons (_, sf)) = sf ()
```

We can now define a sequence containing all numbers:

```
fun numbers n =
  Cons(n, fn () => numbers (n+1))
... fn int -> int lseq
```

Motivation

Larger Examples

- Primes
- Giving Change

# Converting a List to a Lazy List

We want functionality

```
'a list -> 'a lseq
```

which can be accomplished by

```
fun list2lseq [] = Nil
|   list2lseq (x::xs) =
      Cons (x, fn () => list2lseq xs)
```

# Extracting a List from a Lazy List

- ▶ we cannot extract all elements
- ▶ but would like to extract first  $n$  elements

We thus aim at functionality

```
int -> 'a lseq -> 'a list
```

which can be accomplished by

```
fun take 0 ls = []
|   take n Nil = raise Empty
|   take n (Cons(x, sf)) =
      x :: (take (n-1) (sf ()))
```

Running

```
take 7 (numbers 2)
```

thus gives us

```
[2,3,4,5,6,7,8]
```

Giving Change

# Map for Lazy Sequences

Recall that `map` has type

```
('a -> 'b) -> 'a list -> 'b list
```

We want to define `lmap` with type

```
('a -> 'b) -> 'a lseq -> 'b lseq
```

which can be accomplished by

```
fun lmap f Nil = Nil
|   lmap f (Cons(x, sf)) =
      Cons(f(x),
           fn () => lmap f (sf ()))
```

We can now run

```
take 7
  (lmap (fn (x) => x * 2)
        (numbers 1));
```

```
[2,4,6,8,10,12,14] : int list
```

Motivation

Giving Change

# Filter for Lazy Sequences

Similarly, we want to define `lfilter` with type

```
('a -> bool) -> 'a lseq -> 'a lseq
```

which can be accomplished by

```
fun lfilter p Nil = Nil
|   lfilter p (Cons(x, sf)) =
      if p(x)
      then Cons(x, fn () =>
                    lfilter p (sf ()))
      else lfilter p (sf ())
```

We can now run

```
take 7
  (lfilter (fn x => x mod 3 = 0)
    (numbers 1));
```

```
[3,6,9,12,15,18,21]
```

Giving Change

# Non-Fair Merge

Recall the append function

```
fun append (nil , ls)    = ls
|   append (n :: ns , ls) = n :: append (ns , ls );
```

We may want to define

```
fun lappend Nil ls = ls
|   lappend (Cons(x, sf)) ls =
      Cons (x, fn () =>
              lappend (sf ()) ls)
'a lseq -> 'a lseq -> 'a lseq
```

but when running

```
take 7
  (lappend (numbers 100)
           (numbers 1));
```

the second list is ignored:

```
[100, 101, 102, 103, 104, 105, 106]
```

Motivation

Standard Lists  
Higher-Order Functions  
Merging Lazy Lists

Larger Examples

Primes  
Giving Change

# Fair Merge

Instead, we repeatedly swap the two lists:

```
fun interleave Nil ls = ls
|   interleave (Cons(x, sf)) ls =
      Cons(x, fn () =>
              interleave ls (sf ()))
```

which still has type

```
'a lseq -> 'a lseq -> 'a lseq
```

and when running

```
take 7
  (interleave (numbers 100)
              (numbers 1));
```

we do get the desired alternation:

```
[100, 1, 101, 2, 102, 3, 103]
```

```
val primes =  
  let fun sieve (Cons(p,sf)) = let  
        fun p_not_div x = (x mod p > 0)  
          in Cons(p, fn () =>  
                sieve (lfilter  
                        p_not_div  
                        (sf ())))  
        end in sieve (numbers 2) end
```

```
- primes;  
val it = Cons (2,fn) : int lseq
```

```
- take 10 primes;  
val it = [2,3,5,7,11,13,17,19,23,29]  
: int list
```

Giving Change

# Giving Change Lazily

```
fun mk_change coin_vals amount = let  
  (* sol is solution currently built;  
    sf () builds rest of solutions *)  
fun chg _ 0 sol sf = Cons(sol, sf)  
| chg [] n _ sf = sf ()  
| chg (cv1::cvs) n sol sf =  
  if n < 0 then sf ()  
  else chg (cv1::cvs) (n - cv1)  
        (cv1::sol)  
        (fn () =>  
          chg cvs n sol sf)  
in chg coin_vals amount []  
  (fn () => Nil)  
end
```

```
int list -> int -> int list lseq
```

## Motivation

### Lazy Lists

- Conversions to/from Standard Lists
- Higher-Order Functions
- Merging Lazy Lists

### Larger Examples

- Primes
- Giving Change

# Example Changes, I

```
val cg1 = mk_change [5,2] 16
```

We can extract two solutions:

```
take 2 cg1;
```

```
[[2,2,2,5,5],[2,2,2,2,2,2,2,2]]
```

but is there a third?

```
take 3 cg1;
```

```
uncaught exception Empty
```

# Example Changes, II

```
val cg2 = mk_change [25,10,5,1] 46
```

displays the first solution:

```
Cons ([1,10,10,25], fn) : int list lseq
```

We can see that there are 39 solutions:

```
- take 39 cg2;
```

```
val it = [[1,10,10,25],[1,5,5,10,25],...]
```

but not 40 solutions:

```
- take 40 cg2;
```

```
uncaught exception Empty
```
